

Advanced Integration of High Permittivity Oxide for RF-Modules by Layer Transfer Method

T. Riekkinen, T. Mattila, J. Molarius, S. van Dijken, M. Ylilampi, *A. Lüker, and *P.B. Kirby

MOTIVATION

- The development of thin film varactor structures using high ϵ_r oxide (e.g. $\text{Ba}_x\text{Sr}_{(1-x)}\text{TiO}_3$ or $\text{Pb}_x\text{Sr}_{(1-x)}\text{TiO}_3$) for miniaturized RF-module devices
- High electrode conductivity is required to reduce RF-losses!
- Deposition of high ϵ_r layers:
 - At elevated temperatures ($\geq 650^\circ\text{C}$)
 - In oxygen atmosphere
 - Metallic electrode is heavily attacked during oxide growth
 - Oxidation of electrode
 - Grain growth → Poor oxide and electrode quality!
- Options for electrode configuration:
 - Highly conducting noble metals (e.g. Ag, Al, Au, Cu)
 - Not thermodynamically stable during deposition
 - Refractory metals (e.g. Mo, W)
 - Endure high temperature, but are prone to oxidation
 - Refractory metals with diffusion barrier
 - Parasitic effects arise for well-protective layer
 - Conducting oxides
 - Too resistive for RF-applications
- State-of-the-art: Pt
 - Low conductivity $\rho = 6 \times \rho$ of Cu
 - Grain growth and hillock formation
 - Good seed layer for BST growth

SAMPLES

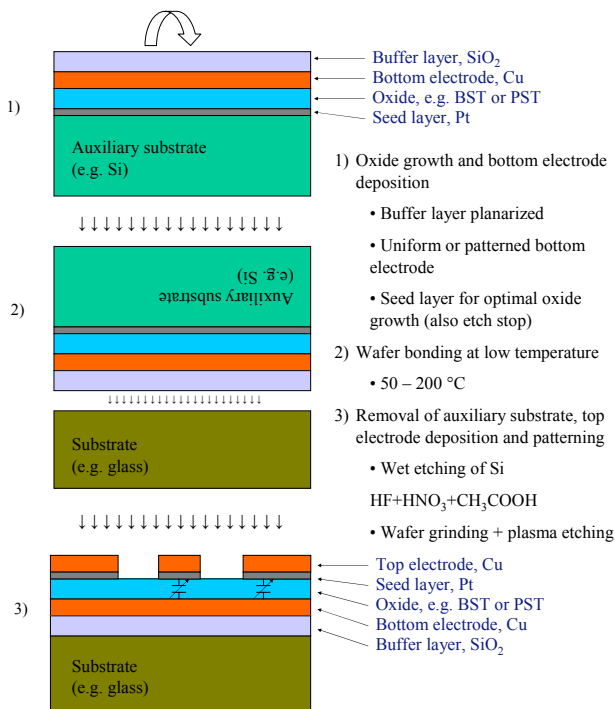

- Substrates: Si/SiO₂ and quartz wafers 100 mm diameter
- Oxide: sol-gel PST ($\text{Pb}_x\text{Sr}_{(1-x)}\text{TiO}_3$) onto Ti/Pt seed layer
 - Annealing 15 min @ 650 °C
- SiO₂ and quartz bonding at room temperature
 - Bond strengthening; two hours at 200 °C

W layer for cleaving
Top electrode, Cu
PST
Bottom electrode, Cu
Buffer layer, SiO ₂
Substrate, thinned quartz

→ Poor adhesion at Pt/PST interface: No Pt in varactor structure!

LAYER TRANSFER

- Both electrodes are deposited at room temperature after oxide growth:
- + Oxide growth under optimal conditions: in oxygen ambient at high temperature
 - + Electrode metal can be freely chosen, e.g. Cu

ELECTRICAL PROPERTIES

Low frequency measurement (1 MHz):

- Large tuning range ~ 4
- 70 V/ μm breakdown field
- Relative permittivity ~ 330

High frequency measurement (0,1 – 2 GHz):

- Preliminary result:
- Q-value ~ 20 @ 1 GHz

CONCLUSIONS

- Degradation of low resistivity electrode is problem when depositing high ϵ_r films for RF-applications
- The problem can be solved by transferring of the high ϵ_r layer to another substrate
 - Oxide growth under optimal conditions
 - Electrode material can be chosen freely: high conductivity and large thickness
 - Substrate that is compatible with RF-applications can be selected
- As a demonstration, sol-gel PST successfully transferred: large tuning range ~ 4 with relative permittivity of 330
